

<h1>Connexion s uris  sur un site web</h1><p>Cet article est un rappel concernant la s urisation de la connexion   un site web.</p><p>J'aborde bri ement le stockage des mots de passe des usagers, la connexion des utilisateurs et le changement de leur mot de passe. Nous allons voir ici une technique simple   mettre en  uvre pour assurer un minimum de s urit    l'utilisateur et lui  iter des ennuis en prenant au s ieux ces donn s et leurs traitements.</p><p>Tout d'abord, il faut savoir qu'un utilisateur a des comptes sur plusieurs sites internet et qu'il utilise souvent le m me nom d'utilisateur et mot de passe sur les diff ents sites. On doit donc s uriser nos donn s pour qu'une intrusion ou une faille ne permette   un tiers de mettre la main sur ces donn s.</p> <p></p><h2><u>1) Stockage des mots de passe des usagers</u></h2><p>Le plus souvent, on utilise une base de donn s pour stocker les mots de passe de tous les utilisateurs pour avoir un traitement automatis  de l'information le plus efficace et rapide que possible.</p><p>En th orie, seul vous pouvez vous connecter   votre base de donn s pour la consulter. En r alit  vous ne pouvez pas le savoir. En effet, si votre site ou le serveur sur lequel il se trouve a    compromis, une autre personne peut avoir r up  des informations issues de votre base de donn s ou avoir mis la main sur les codes de connexion   votre base.</p><p>Il faut donc  iter de stocker directement les mots de passe dans la base. En r alit  m me un cryptage du mot de passe n'est pas possible puisque la cl  et l'algorithme seront disponibles pour l'intrus.</p><p></p><p>Il ne reste plus qu'une seule solution, stocker une empreinte du mot de passe. Habituellement, on le fait avec une fonction de hachage qui va cr er un r sum  du message et qui ne permettra pas de retrouver le mot de passe original.</p><p>A ce niveau, plusieurs fonctions sont disponibles comme MD5 ou SHA1. Je vous conseille de rechercher si la s urit  de la fonction que vous utiliserez est toujours bonne. En effet, les techniques  oluent et les puissances de calculs disponibles augmentent rapidement. Au moment o  j'ai r ig  cet article, la fonction MD5 n'est plus s uris  puisqu'il est maintenant possible de cr er un mot de passe clair qui correspond   votre fonction. En ce qui concerne SHA1, il fait l'objet d'attaques r urrentes et il devrait surement bient  tomber.</p>{mooblock=Mise en place (cliquez pour voir)}<p>Voici la partie serveur d'un code simple qui permet de mettre en pratique un GDS. Il vous reste   vous cr er une fonction rand_str() bien   vous. Moi ici, j'ai une fonction qui va g ner une chaine une cha e al atoire de taille 40 caract es.</p>{codecitation class="brush: php; gutter: false;"}if (isset(\$_SESSION['gds']))

Connexion des utilisateurs

Sachant que vous ne contrôlez pas le réseau entre votre serveur et l'utilisateur, on ne peut pas transmettre en clair un mot de passe. Celui-ci pourrait être intercepté par une machine sur le réseau. On appelle cette technique l'attaque

man in the middle puisque c'est une personne qui s'intercale entre les 2 ordinateurs.

Donc, le plus simple serait-il de calculer le hash du mot de passe côté client en JavaScript et de l'envoyer ? La réponse est NON!

En effet, il suffit à la personne qui intercepte la communication de renvoyer les mêmes données pour être identifié à la place de l'utilisateur. Le mot de passe est alors devenu une chaîne qui sert un générateur de mot de passe et le hash lui est devenu le vrai mot de passe. Alors comment faire pour identifier un utilisateur ?

Il faut utiliser la technique du Grain De Sel. Le principe :

- 1- A l'affichage de la page de connexion par l'utilisateur, on va générer une chaîne le plus aléatoire possible qui changera à chaque fois qu'un utilisateur affiche cette page. Pour en garder une trace, on peut sauvegarder ce GDS dans la session de l'utilisateur.
- 2- Hash en JavaScript du mot de passe côté client.
- 3- Concaténation du hash obtenu avec le GDS.
- 4- Hash de la concaténation obtenu en 3.
- 5- Envoi du résultat

Ainsi, à chaque fois que l'utilisateur se connectera, la chaîne servant à l'identification du mot de passe change et une personne tout au long de la ligne ne peut pas deviner

le mot de passe m[od]ifie s'il connait le GDS.</p><h2><u>3) Changement de mot de passe</u></h2><p>Si un utilisateur oublie son mot de passe ou si on veut lui laisser la possibilit[é] de le changer, le m[od]ifie probl[ème] se pose sauf que cette fois si, on ne pourra pas utiliser un hachage associ[é] à un Grain De Sel pour r[é]cup[er]er le mot de passe puisque cette technique permet uniquement de v[er]ifier si un mot de passe est correct.</p><p>J'ai donc mis au point un syst[ème] qui g[én]ère des cl[és] de cryptage [et] chaque fois que l'utilisateur demande [à] modifier son mot de passe pour utiliser un chiffrement asym[étrique] RSA. e syst[ème] ne peut pas [être] utilis[é] chaque fois qu'un utilisateur se connecte car il demande beaucoup plus de ressource au serveur. Il doit [être] utilis[é] avec parcimonie.</p><p>{mooblock=Voici un exemple d'utilisation : (cliquez pour voir)}</p><p>{codecitation class="brush: php; gutter: false;"}include_once("rsa.php");

La 1ère modification utile est d'ajouter une chaîne au mot de passe avant de le hasher pour qu'au final, celui-ci soit unique dans votre base de données même si l'utilisateur utilise le même ailleurs.</p><p>Ensuite, pour que votre site soit vraiment sécurisé ne vous connectez pas en FTP pour envoyer vos fichiers sur le serveur. En effet, à ce moment là le mot de passe transit en clair sur le réseau. Si votre hébergeur vous fournit un accès SSH, utilisez le SFTP pour sécuriser votre transfert.</p><p>Vous pouvez aussi utiliser un certificat SSL (https) si vous en avez un.</p></div><div data-bbox="868 949 923 963" data-label="Page-Footer"><p>11 / 11</p></div>
